Thoughts and Most Helpful Exercises

This is a personal "journal" of my progress through *Graph Theory by Bondy and Murty*. I am doing this for my own personal growth, as I have always felt a little lacking in discrete mathematics. Note that these are my personal solutions and have not been reviewed so some of my proofs may be wrong! As for the structure of my solutions, I denote questions that I have not yet answered in red and particularly difficult questions with a bold *. My plan of attack is as follows. On my first pass, I will complete all exercises denoted with a star ★ as well as one or two of the challenge exercises in each subsection. These will be marked with a (1) for my first pass. In a second pass of the textbook, I will work through other exercises that interest me (additional challenge problems and any other fun problems).

Below I discuss some topics that I found particularly challenging/interesting and the exercises that best helped me understand the material at a deeper level.

Helpful Questions per Section

- Section 4:

Final Thoughts

Chapter 1: Graphs

1.1 Graphs and Their Representation

P.1) (1st pass) Let G be a simple graph. Show that $m \leq \binom{n}{2}$, and determine when equality holds.

SOLUTION: A fully-populated graph is one that is complete. This means that we want to count the total number of ways that we can create pairs from n vertices. This is exactly $\binom{n}{2}$. Therefore, equality holds when the graph is complete. If the graph is not complete, $m < \binom{n}{2}$.

P.3) (1st pass) Show that a) every path is bipartite, b) every cycle is bipartite if and only if its length is even

SOLUTION:

a) Let p be a path $v_1 \dots v_n$ in a graph G . Define $X = \{v_i \mid i \text{ odd}\}$ and $Y = \{v_i \mid i \text{ even}\}$.

Clearly, X and Y form a bipartition of the path p because for $v \in X$, $v = v_k$ for k odd so $v_{k+1} \in Y$ or $v_{k-1} \in Y$. We say “or” to account for the case where v is the start or end of the path. The same reasoning can be applied to $v \in Y$.

b) (\leftarrow): Suppose a cycle $v_0 \dots v_k$ has even length. Therefore, k must be odd since the total number of edges must be even. Apply the same bipartition as problem 1.1.1 so $X = \{v_i \mid v_i \text{ odd}\}$ and $Y = \{v_i \mid v_i \text{ even}\}$.

For $v \in X$ where $v = v_i$, we know that $v_{(i-1)}, v_{i+1} \in Y$ (if $i = k$, let $i + 1 = 0$). We can apply the same logic to $y \in Y$.

(\rightarrow): suppose the length of a cycle is *not* even so suppose the cycle is $v_0 \dots v_k$ for k even. We can construct a bipartition with empty sets X and Y . Start from v_0 without loss of generalization.

Define the following algorithm to construct a bipartition.

Algorithm 1 Construction of Bipartite Set

$X := \{\}$

$Y := \{\}$

$L := [v_0, \dots, v_k]$ for k even and L a queue

▷ use a queue since $\deg v = 2$, we can only move forward or backwards in the cycle. WLOG, move forward

while L not empty **do**

$v := \text{POP}(L)$

if v adjacent to $u \in Y$ or Y empty **then**

$\text{ADD}(X, v)$

 ▷ the index of v will be even

else if v adjacent to $u \in X$ or X empty **then**

$\text{ADD}(Y, v)$

 ▷ the index of v will be odd

else

return error

end if

end while

This algorithm will always return an error because when we get to v_k , v_k is adjacent to v_0 . Therefore, there will be an edge $v_k v_0$ with both endpoints in the same partition X .

P.9) (1st pass) Let $G[X, Y]$ be a bipartite graph.

a) Show that $\sum_{v \in X} d(v) = \sum_{v \in Y} d(v)$,

b) Deduce that if G is k -regular, with $k \geq 1$, then $|X| = |Y|$.

SOLUTION:

a) Let m be the number of edges. Because $G[X, Y]$ is bipartite, we know that for all $e \in e(G)$, one endpoint $v \in X$ and another $u \in Y$.

Therefore, we cannot have $\sum_{v \in X} d(v) \neq \sum_{v \in Y} d(v)$, because then that implies that there is an edge with both endpoints in either X or Y .

- b) Suppose that G is k -regular with $k \geq 1$. This means that for all $v \in v(G)$, $\deg(v) = k$. Therefore, we get the following...

$$\begin{aligned} \sum_{v \in X} d(v) &= \sum_{v \in Y} d(v) \\ \sum_{v \in X} k &= \sum_{v \in Y} k \\ k(\#\{v \in X\}) &= k(\#\{v \in Y\}) \\ |X| &= |Y| \end{aligned}$$

P.10) (1st pass) A k -partite graph is one whose vertex set can be partitioned into k subsets, or parts, in such a way that no edge has both ends in the same part. (Equivalently, one may think of the vertices as being colorable by k colors so that no edge joins two vertices of the same color.) Let G be a simple k -partite graph with parts of sizes a_1, a_2, \dots, a_k . Show that $m \leq \frac{1}{2} \sum_{i=1}^k a_i(n - a_i)$.

SOLUTION: Let's first decipher what $a_i(n - a_i)$ means. Let's say there are k colors. The expression $a_i(n - a_i)$ is equivalent to counting the total number of possible edges between vertices of color i and all other colored vertices since for each vertex of color i , we can have an edge between any of the $n - a_i$ vertices not of color i .

As such, if we sum $a_i(n - a_i)$ across all k colors, this is similar to counting the degree of a complete graph except we want to exclude edges between vertices of the same color.

However, there is a caveat. We want to prevent double-counting because if we continue the procedure above for all colors, we effectively double-count all the edges in a complete graph. This is because, for $a_j(n - a_j)$ with $j \neq i$, we count the total number of possible edges between vertices of color j and all other colored vertices. This is equivalent to counting the total number of possible edges between vertices of color j and all vertices of color i **and** all other colored vertices. We already counted the total number of possible edges between vertices of color j and all vertices of color i via the calculation $a_i(n - a_i)$.

Therefore, $m \leq \frac{1}{2} \sum_{i=1}^k a_i(n - a_i)$.

P.11) (1st pass) A k -partite graph is complete if any two vertices in different parts are adjacent. A simple complete k -partite graph on n vertices whose parts are of equal or almost equal sizes, $\lfloor n/k \rfloor$ or $\lceil n/k \rceil$, is called a Turan graph and denotes $T_{k,n}$.

- a) Show that $T_{k,n}$ has more edges than any other simple complete k -partite graph on n vertices.
b) Determine $e(T_{k,n})$.

- a) We can use question 1.1.10's result on k -partite graphs. Specifically, we know that for a complete k -partite graph, $m = \frac{1}{2} \sum_{i=1}^k a_i(n - a_i)$. This problem is equivalent to maximizing m subject to the constraint that $\sum_{i=1}^k a_i = n$ and $0 < a_i < n$.

$$\sum_{i=1}^k a_i(n - a_i) = n - 2a_i$$

- b) Let's consider the simplest case of a'_i of equal sizes to $a'_i = n/k$. Then, $e(T_{k,n}) = m = \frac{1}{2} \sum_{i=1}^k a_i(n - a_i) = \frac{1}{2} \sum_{i=1}^k \frac{n}{k} \left(\frac{k-n}{k} \right) = \frac{n(k-n)}{2k}$.

If a'_i are of almost equal sizes, Then

$$\begin{aligned} e(T_{k,n}) = m &= \frac{1}{2} \sum_{i=1}^k a_i(n - a_i) \\ &= \frac{1}{2} \left(\sum_{i=1}^k (\lfloor n/k \rfloor)(n - \lfloor n/k \rfloor) + \sum_{i=1}^k (\lceil n/k \rceil)(n - \lceil n/k \rceil) \right) \end{aligned}$$

P.1) (1st pass)

20.4 The Matrix-Tree Theorem

P.1) (1st pass)

P.2) (1st pass)

P.3) (1st pass)

P.4) (1st pass)

20.5 Resistive Electrical Networks

P.1)

20.6 Perfect Squares

P.1)

20.7 Random Walks on Graphs

P.1)

Chapter 21: Integer Flows and Coverings

21.1 Circulations and Colorings

P.1) (1st pass)

21.2 Integer Flows

P.1) (1st pass)

21.3 Tutte's Flow Conjectures

P.1) (1st pass)

21.4 Edge-Disjoint Spanning Trees

P.1) (1st pass)

21.5 The Four-Flow and Eight-Flow Theorems

P.1) (1st pass)

21.6 The Six-Flow Theorem

P.1) (1st pass)

21.7 The Tutte Polynomial

P.1) (1st pass)
